

Front-end development: The DOM

JavaScript – selecting all elements

The following exercise contains the following subjects:

- functions

Instructions

You have these elements in your HTML file:

```
<div id="myFirstDiv"></div>
<div id="mySecondDiv"></div>
<div id="myThridDiv"></div>
<div id="myFourthDiv"></div>
```

Somebody selected the elements and stored them into individual variables like this:

```
const myFirstDiv =
document.querySelector("#myFirstDiv");
const mySecondDiv =
document.querySelector("#mySecondDiv");
const myThirdDiv =
document.querySelector("#myThridDiv");
const myFourthDiv =
document.querySelector("#myFourthDiv");
```

Is there a better way you can store the individual elements with giving them different names?
